There is no such thing as a one man show in the engineering profession. Vertly, many people have given so their willing and able support during this project. Principle among these has been my thesis committee. Dr. Gary Lamont as chairman provided much guidance as this my most ambitious project began. Being a software oriented person by trade and hobby, I had never gotten much involved with hardware at the chip level. Dr. John Borky as a committee member provided me with several important insights into the performance of various chips of the MOS variety.

Dr. Walter Seward, the other committee member, helped me to get started on the DEC System 10, the primary tool of this investigation.

All three proved quite patient with my naive beginnings and later with my attempts at writing.

Money and resources must come from somewhere and these were eagerly provided by the two sponsors. Mr. John M. Acken;
Sandia National Labs; Dept 2113; Albuquerque, NM, 87185 gave me much of his time and a gate level digital systems simulator which he maintains. He also welcomed me to his home and office during my TDY to Sandia Labs. His suggestions as to what needed to be accomplished provided the initial framework for the project.

Capt. John B. Rawlings; AFWAL/AADE-3; WPAFB, OH, 45433 was the other sponsor. He and his colleagues: Mr. Mike Mills, Lt Eric Smith, Mr. Rick Stormont, Lt. Joe Tatman, and Lt. Mike Tebo gave constant feedback on the real world requirements of Computer-Aided-Design. They were always ready

with their time and followship. Capt. Rawlings' initiatives at AFIT opened the door for this investigation. His division, headed by by LTC. Gary Principle, caw to the availability of the DEC System 10 and a well equiped office.

The library services of AFIT were superb. Mrs Molly Bustard always assisted as her shelves were gradually emptied. She helped in finding books and in long term withdrawals. Mr. Stan Boyd gave his excellent aid to the filling of requests for quite a number of backdated journal articles. What our library did not have, he searched the world for.

During their inception, many projects benefit from the counseling of people who have a good feel for what will be acceptable and what will not. In this regard my thanks go out to Dr. Tom Hartrum, Dr. Kenneth Melendez, and Dr. Jim Rutledge.

Not to go unmentioned are two very fine technicians in AFIT's labs.

Mr. Dick Wager and Mr. Dan Zambon saw to it that books and equipment held

by their department were made available. They also gave informative

discussions on the acutal use of MOS chips.

Also there is Mr. Mike Culp, a high school student who studied computer programming under my tuteladge. He produced several of the descriptive drawings that were needed.

Finally, but certainly not in the least is my dear friend and colleague Capt. Nadine Levine. Her intuition helped me to solve the several problems which bedevil thesis students. Her never ending encouragement made doing this thesis much easter.

To all of these people I owe my sincere gratitude.

Peter of Routh

exist, one can not easily integrate the two due to their inherent limitations. A given simulation can not be described partially in gate level and partially in a higher level. A solution is to create a functional level preprocessor and a library of functional device models linked to a gate level simulator's input language. This permits the mixing of behavioral models with gate level models in the same system structure. The combination of processes (element models or primitives) and their structure (interconnections) can be exercised all at one time during a single simulation session. From the start, there came forth an obvious method which could be used to intermix the several levels of modeling (*).

Two separate pieces of software were written to implement a specific solution to the above stated situation. SISL, Structural Interface to the Salogs Language was created. This is a functional level preprocesor to SALOGS (SAndia LOGic Simulator) which is an eight-state, MOS, gate level digital systems simulator. SISL will accept functional level systems descriptions and convert them to a form acceptable to SALOGS.

The other effort was the building of a functional level modeling library. This library consists of three behavior models: a 4-16 decoder, a 2048 X 8 ROM, and a 256 X 8 RAM. These models are designed to be used in a functional level/gate level model of a digital system and will link to the SALOGS run time system. Together, these two programs (SISL and the modeling library) provide the easy use of the top-down approach to digital system design. Thus, the project's culmination.

(*) See Chapters 3 and 7 for more on the hierarchy of digital systems modelling. The result of this investigation was the new collist, to easily mix functional and gate level moments during the same simulation run. Any new ray be decorable to in functional and gate level principles. This is necessary because the USAF is constantly increasing its use of very large scale integrated circuits (VLSI). It is unconscioul to simulate systems which use these circuits at the gate or register transfer levels due to the computer and human resources required.

Gate level simulation along with register transfer level descriptions has been the bread and butter of computer aided logic design [H2,86].

Until the present time, eight-state, gate level simulation of digital devices has sufficed for the development of most logic circuits. The eight states are: low level, undefined, high impedence, high level, negative slope, transient undefined, transition to high impedence, and positive slope [A1,12].

In the past, many simulator packages have been restricted to gate level models because the state of the art would not support more general types of modeling [S9,25]. This restriction has caused many problems as the state of the art in digital device construction has improved.

PROBLEM

One of the major problems of digital simulation is that large systems are prohibitively difficult to describe and simulate at the gate or register difficult to describe and simulate at the gate or register transfer levels. transfer levels. The desire, therefore, was to create a new level of simulation called the functional level [H2,86].

At this level the designer can specify subsystems such as ROM, RAM, busses, shift registers; in short, logical devices of arbitrary complexity. Functional level modeling, as addressed by this investigation, is meant occurs during the "...circuit description language..." phase of the typical CAD (Computer Aided Design) run.

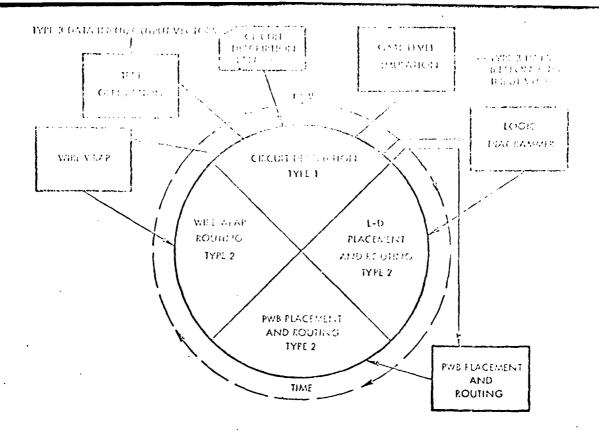

FIG CH1-1

A TYPICAL CAD RUN (C8,292)

The modeling and simulation of a digital system follows a pattern which enhances the use of machine assistance. Material developed via simulation can be used in the actual implementation as well. Fig CHI-I [C8,292] depicts the simulation proces. The intent is to affect only the indicated phase and to let the rest of the simulation to proceed as if no modifications had taken place. At this phase functional/gate level models are described, not just gate level models as in the past. SISL does its work at this node and SALOGS picks up the process at the "...gate level simulation..." node.

GOAL

It should be possible to allow computer designers to focus on certain portions of a digital system's logic while ignoring details of other portions. Designers should be able to "black box" certain portions of a big system. At times it will not be known what the future contents of a module will be, only that it will have to exist in the system.

The results of this study should allow the designer to choose which blocks to describe at the gate level and which to describe at the functional level. A person would thus be encouraged to follow a top-down design methodology. A preprocessor to the gate level simulator should handle the connections between the two levels of descriptions.

It is possible to develope software which can give a great deal of help to the designer during any attempts at higher level models and simulations. The above goal was met by designing a library of functional level subroutines. A functional level preprocessor was also developed. The preprocessor accepts digital descriptor input and converts it to a form which logically links the subroutine library to the input language of a commonly used gate level digital simulator. Such a common industrial simulator is found in SALOGS, an eight-state computer-aided-design (CAD) system developed at SANDIA LABS [C2,1] [Appendix D].

Salogs allows the user to describe models composed of MOS gate level primitives (AND, OR, etc.) and to perform simulations using those models. It will also do fault analysis. Another feature is a capability to accept subroutines which are callable as modeling primitives.

This approach to the realization of the goal must necessarily be clearly defined as to what may be expected of it.

The preprocessor mentioned above does not convert functional descriptions into gate descriptions. It does, however, create the logical linkages to the SALOGS input language so that pin connections, device names, and other parameters required by SALOGS are made consistent with the users' gate level portion of the overall system being modeled. The preprocessor delivers two outputs based on the functional level description it receives: functional identifiers required by SALOGS and a model specifying the overall functional system. From these outputs, the preprocessor creates a file of functional descriptors which can be appended to the gate level portion of the users' description.

The user must identify his interconnections to the preprocessor's circuit. Since SALOGS allows the linking of subroutines to its own code, no modifications have to be made to SALOGS itself. The software is run in batch mode due to the extended amount of wall time and core required by the SALOGS software (*). To ensure portability, the project was done in ANSI 66 standard FORTRAN IV, the same as SALOGS itself.

The library of functional models is written to deliver useful information to the designer. These models (which account for all eight states), under specific inputs will indicate that an unspecified input has occured rather than behave as the real circuit would.

There are some o Ther ideas and features which should be presented.

These have to do with the development of the software and techniques

of functional level modeling.

(*) Wall time varies according to how many jobs are currently being handled by the computer system. Core is constant at around 200K for each program in the SALOGS/SISL series.

The body of this thesis is concerned with three ideas: digital modeling in general, the methods of functional modeling, and the internal workings of the SISL preprocessor.

Chapter 2 gives an introduction to some of the basic ideas used by those who actively engage in the simulation of digital systems.

Some approaches to the subject are generally accepted in the simulation community as standard and this chapter reviews these.

Chapters 3 and 4 discuss the top-down method of digital system design and its specific application to this project.

Chapters 5 and 6 present some general methods of creating behavioral models of digital devices. These were developed for use in this investigation and are applied to the modeling library.

In Chapters 7 and 8 one will find an overview of digital system representation levels and a few of the languages used to work at one or more of those levels. SISL is an application of the ideas found in these other digital system description languages.

The thesis closes with the summary and conclusions found in Chapter 9.

These presentations are supported by an Appendix and Glossary. In the Appendix will be found users' guides to the various software, listings of the SISL and modeling programs, sample runs, and flowcharts. The Glossary defines the specific terms used and will clear up any confusion as to their meaning.

This chapter reviews some of the basic approaches to digital systems simulation. It begins with a definition of what computer aided design should accomplish and goes on to the general ways in which one may employ simulation techniques for digital systems. A summary provides information on the current uses of simulation.

DISCUSSION

Because of the complexity and economics of today's digital systems, a design tool is needed that will allow the error free analysis and testing of circuit implementations (*). This tool should not require the physical realization of the circuit. Such a tool has been found in the form of a computer running a piece of software which will exercise a digital system that has been described in the input to that software. Programs of that nature performing computer-aided-design (CAD) permits the digital designer to submit his circuit ideas to strict and nearly complete simulation and analysis without having to physically construct the hardware.

Many such simulation tools exist today [B2,1] [C2,1] [V1,1] [V3,1]. (See the Bibliography for papers on specific languages.) They provide an entrance to the solution of modeling problems. Most of the larger companies in the computer industry are involved in CAD research. Among these is IBM [B1,20].

(*) Unless otherwise noted, the references for this chapter are found in the works by Acken and Case listed in the bibliography.

The simulation of a digital system is the description of the system model in an appropriate computer language along with the computer's experimentation with that model. Through the use of CAD software, a circuit description and operating parameters are taken as input, with experimental and statistical results of the circuit simulation as output.

TWO GENERAL TYPES OF SIMULATION

There are two general types of logic simulation: True-Value Analysis and Fault Simulation. A designer using True-Value Analysis is judging the circuit's ability to perform according to the original specification of the design criteria. Fault Simulation is employed to observe system operation under various forms of circuit flaws.

(TRUE-VALUE ANALYSIS) In its most fundamental form, True-Value Analysis is the acceptance of the logical description of a circuit, the application of logical values (l's or 0's) to the circuit's inputs, and delivering as output the Boolean result of the combination of circuit and inputs.

An extension of simple Boolean modeling in terms of the binary values 1,0 is to add a state to the simulation called a DON'T KNOW or UNDEFINED (or *). This unknown logic state is distinct from a DON'T CARE whose logic level can be either 1 or 0 with no affect on the operation of the circuit.

Given smaller and smaller time steps, the time it takes a voltage to rise to the 1 level or fall to the 0 level becomes important. As digital circuits become faster and faster, the timing issue becomes more important. Thus, more advanced simulators use three extra states:

D, negative slope; U, positive slope; and X, transition undefined.

Six-state simulation allows the computer modeling of very fast digital systems without worrying about the particular technology to be used in the actual system construction. Some simulators (SALOGS for one) do incorporate MOS technology in their software. These simulators employ two additional states result in an eight-state simulation. Those two states: H, high impedance; and A, transition to high impedance are used to simulate a device being effectively off-line.

Digital simulators which model various other technologies usually have the ability to be set for four- or eight-state mode. In four-state mode, the model operates using, high, low, undefined, and high impedence. Eight-state mode simulates using the added states of negative slope, positive slope, transition undefined, and transition to high impedence (See Appendix D).

(FAULT SIMULATION) Fault simulation is performed to derive a set of input signals which can then be used as stimuli to test the functioning of a logic network. These signals form a test pattern which can be auutomatically generated by the simulation software. When these signals are placed on a circuits' input, they allow the detection of certain defects [T3,38]. Usually, single "stuck-at" fault modeling is used due to the difficulties of multi-fault modeling. In this method, only one defect is assumed and it is a particular signal being "stuck at" or a "never changing" value. Either one of the module's outputs is stuck or one of its inputs is stuck. There are four ways to simulate a fault: fail-all simulation, which will fail all outputs one at a time; parallel fault simulation, which simulates several faults at once; deductive fault simulation, which lists faults which cause a change in the output of a given module compared to the unfaulted circuit; and concurrent faulting, which only simulates the parts of the faulted circuit whose inputs, outputs, or states do not agree with the unfaulted circuit.

Since it has become so expensive to build and test unproven hardware, computer simulation of digital circuits is being employed more often by the military and industry. Since design correctness can be verified without actual hardware realization, the cost of design and implementation is cheaper than it would be if computer simulation were not used. Simulators make it possible, without risk to a physical circuit, to study and experiment with a system or subsystem. (There is, however, a certain financial risk associated with committing a facilities' resources to the simulation task [S9,23].) Simulators make fine pedagogical devices for teaching both students and practitioners the variations of the design and analysis of digital systems. Perhaps one of the most important benefits from an engineering point of view is that they allow systems to be exercised under expanded, compressed or normal timing. Overall, they permit the designer to judge his designs conceptually without actually having to build them.

Work on such design aids has been pursued by Sandia Laboratories

(Albuquerque NM), the Avionics Laboratory of the Wright Aeronautical Labs

and A r Force Institute of Technology (Dayton, OH), to name a few. As more

and more standard models of low level devices are created, digital modeling at

higher and higher levels becomes possible, thus overcoming the bottleneck of

man-years and computer resources required to create simulations of large

scale digital systems.

CH 3. THE BUILDING OF A SYSTEM USING FUNCTIONAL MODELS

A digital system is not simply created in its final form. It is not usually possible to design a working product on the first attempt. Several systems are developed in the course of a development effort. These range from the interconnection of a few high level subsystem blocks to the detail of a gate level or lower model. This chapter introduces the reader to the process of going from the higher, undetailed modeling level to the lower, detailed level.

THE GATE LEVEL AND BLACK BOX BEGINNING

The desire to intermix gate and functional models derives from the hierarchy of a top-down approach to digital systems simulation. In this method, one begins with an undetailed viewpoint of the desired system. This viewpoint is in terms of a few general blocks. As the modeling effort goes on, these blocks are broken down into more detailed sub-blocks. Finally, each sub-block is defined by progressively more complex units until the desired level of detail is achieved.

Thus, the black box is a part of a model which, as yet, does not perform as it ultimately will. It can be connected to more detailed portions such as a block described in gate level detail. There is a certain technique to using this mix when simulating with SALOGS.

SALOGS has the capability to "SET" the value of any of its nodes.

(For more discussion on SALOGS see the SALOGS USERS GUIDE in the Appendix.)

Such nodes will retain their set value regardless of system operation.

Therefore, the designer can allow the black box to either deliver some default output for any input or deliver a SALOGS set output. The model may then be studied under various conditions which may be eventually produced by the future contents of the box. The default outputs can be used to flag the fact that the box would have had some effect on the systems' operation.

EXPANDING THE BLACK BOX

Gradually, decisions will be made as to the required output of the box given certain inputs. Now the functional model may be expanded to produce that output when the stated inputs occur. A default to some flagging output (such as undefined) can be arranged for non-specified inputs.

As more data is gathered and greater detail is developed, the black box becomes a true functional model performing very nearly as its gate level counterpart would. It has the advantage of using less core and time to run and it ignores some of the unwanted or unneeded detail attendant to gate level models. It can be expanded to any desired level of detail depending on resources and the needs of a given simulation.

CH 4. SIMULATING BI-DIRECTIONAL LINES

SALOGS, the gate level modeling software, has some particular requirements when bi-directional lines are called for. This chapter introduces the background s of such lines and continues with the detailss of their simulation in SALOGS.

INTRODUCING BI-DIRECTIONAL LINES

As chip manufacturers have heaped complexity upon complexity, the number of pins necessary for I/O has increased. Fourty pins has generally become the acceptable maximum standard but some chips would require more than that. Because of this, certain pins have been designed to carry data in both directions. These pins thus make it possible to have fewer connections to a chip while keeping the original number of options.

The issue of bi-directional lines should be addressed. If a design aid is to maintain its capability to deal with state of the art systems, it must accommodate the devices which make up those systems.

SALOGS itself will not allow the direct use of bi-directional lines. Nodes are either input or output but not both.

Without modification to the SALOGS package, it is not possible to truely simulate bi-directional lines. However, by using a buss model and splitting each two-way line into one input and one output line, one can still model devices with such lines. Along with this, one can incorporate timing and clocking and delay parameters in the buss. (The behavioral models themselves do not contain these parameters.)

Such a splitting out of bi-directional lines has not proven to be a drawback to the modeling effort of this investigation. The RAM and ROM models to be discussed later use line splitting.

The buss model also solves a problem caused by the way SALOGS updates nodes. Nodes are updated sequentially, one at a time each time step. When bi-directional lines are used the wrong item could be updated first. Let us say, for instance, that the CPU is talking to the RAM. If the RAM is updated first then the CPUs' input is not properly considered. The buss is last to be updated so that the RAM and CPU get correctly updated in the next time step. SALOGS is caused to update the buss last when the user lists the buss last in a system description.

The buss model could be expanded to also handle buss contention. While SALOGS can easily handle the fanout of output lines, it can not describe the fanin of input lines. Only one output node can talk to any given input node at any one time. If input to a given node can come from more than one output node, some buss control must take place.

-

A SALOGS bi-directional buss can be written as a behavioral model to handle several simulation requirements. The most important of these are two-way lines. These are followed by timing, clocking, and delay parameters. One final item is the description of a buss contention controller.

CH 5. CREATING A CHIPS' BEHAVIORAL MODEL

Several Issues must be considered when writing software which describes a behavioral model. It is not a straightforward task to construct such a program. Presented in this chapter are the methods used and the considerations taken in creating the behavioral modeling library.

COMPLEXITY VS. DETAIL

Many are the ways to create a behavioral model. Each method has its own advantages and drawbacks.

Let D= detail of simulation

C= device compexity

K= a constant representing computer and human resources

Then D \star C = K would be an excellent conceptual formula for describing the various limitations to face when modeling a digital system (\star). The overall goal of modeling is to simulate in great detail very complex devices while minimizing core and human involvement.

These ideas are very much at odds with each other. As the complexity of the device increases, the limitations of computer and human resources prevent the simulation of a great amount of detail. Conversely, if a large amount of detail is required the same problem will not allow the modeling of complex devices. As the available human and computer resources increases or decreases so can detail and complexity to a proportional degree.

The following sections review several methods of creating behavioral models. These were developed in the course of the attempts made to create an elonomical yet detailed behavioral modeling library. There will be as a for tradeoff evident in that, while a particular method may be easy to implement, it may not always yield an economical or otherwise usable model.

(*) This formulation was originally suggested by the sponsor, Rawlings.

19

シーを

The fastest way to derive an output from an input is to map the input to a location in a table which contains the corresponding output.

It is helpful to assign a number to each of the eight states that any given node may attain:

SALOGS Assignment	FORTRAN Assignment	State		
***************	\$100 and 100 100 top 100 100 100 100 100 100 100 100 100 10		The cost and the size	
0	1	0	False	
1	2	*	Undefined	
2	3	H	High Impedance	
3	4	1	True	
4	5	D	Downward Slope	
5	6	X	Transient Undefined	
6	7	A	Transition to High Impedance	
7	8	U	Upward Slope	

When SALOGS fixes a node value it uses these assignments.

These must be converted to the FORTRAN assignments for array table access. As an illustration, consider a box which has two inputs and two outputs. The inputs can be modeled using a two dimensional table which is 8 X 8. The output lines are modeled the same way only with an 8**2 X 2 table. There are 8**2 output possibilities due to the 8 X 8 possible input arrangements. The following is an example of how the array tables are used to model the box. Let input-line-l be in state A and input-line-2 be in state U. This will cause a certain resulting output. SALOGS will represent the input event as 6,7. The input table will be accessed using (6+1,7+1). Contained in that location is the row of the output table which holds

the required output line values. Each column of the output array holds a state for a designated output line. In general terms, an 8 X 8 x...x 8 input table maps to an 8**N X K output table where:

N= # input lines K= # output lines

If K=1, then the value found in the input table is the state of the output line. States assigned to output lines are SALOGS assignments.

In this case, due to the stated behavior of the box, there may not be 8**2 unique output arrangements. If that proves true, the output table may be shrunk accordingly to an M X 2 array; where M is the number of unique outputs. M's maximum value is 8**2. The input table remains the same size, but any given location could hold the same value as another. In general, there is a maximum of 8**2 unique outputs; where

Z is the number of output lines. Also, it may not matter which is input-line-1 and which is input-line-2. In other words, (input-line-1 +1,input-line-2 +1) may always yield the same value as (input-line-2 +1,input-line-1 +1). In that case only the upper or lower triangle of the input matrix would be needed. In FORTRAN, though, it is not possible to dimension a triangular array. If carefully documented, the unused portion of the input table could be applied to some other activity, thereby achieving a savings in core.

Once the output array has been accessed, one needs to find there the values which correctly define the devices behavior.

(DERIVING THE OUTPUTS) The next question involves exactly what outputs are required from all the possible input combinations. For an original circuit, a knowledge of the chips' technology and configuration would be the key. For premanufactured circuits, there is available an industrially proven and tested gate level modeling package, SALOGS. Its primitives (AND, OR, NOR, etc.) are fully defined MOS models. They will deliver a correct output given any combination of the states as input. With this package one could model a device at the gate level, apply all possible input combinations, and thus receive a corresponding list of outputs. This list can then be used to load the output table. The gate model need be run only once. Its results can be held in off-line storage until the data is needed to load the

A problem with the above technique is that a gate level model taken from a data book is only a logical model, not an operational one. Also, it would be extremely difficult to model, say, a 64K RAM at the gate level. So there are limitations to just how far one can go with this method. Too, as the chip becomes more complex, a lot of core is required to represent the I/O tables. (A five input OR gate requires 8**5 array locations.) On the other hand, not much time is used in the simple array mapping process. These problems can be, in part, overcome by the following technique.

output arrangement, the I/O tables can be collapsed accordingly.

Equations, both arithmetic and logical, would be then required to recognize the states which cause fixed outputs. Other arguments would be needed to map the other input combinations to the reduced tables. For example; consider the five input OR gate which used 8**5 array locations. Employing a combination of equations and tables this can be reduced to 7**5. A true on any input line causes a true output in an OR gate. Similar thoughts affect the multiple input AND gate. Any input being false will cause a false output.

Depending on how many states cause constant outputs, this method may use less core than the previous one. However, the designer must deal with the state recognition and mapping equations. These logical/arithmetic computations may consume more time and core than the simple direct mapping arguments.

Experience has shown, however, that this method presents important advantages over the simple table driven models. It is possible to carry the use of equations even further as the next method will demonstrate.

TRUTH TABLE/LOGICAL EQUATION DRIVEN MODELS

Devices of lesser complexity than, say, a CPU are described in the data books by a truth table. Since logical AND and OR functions are a part of the ANSI standard FORTRAN, it is possible to write logical expressions to represent output vs. input. These equations take the form ABC+(-A)BC=O and so on; where the left hand side is input and the right output. Each input value is stored in its binary form (3=011 for instance.) A logical manipulation of the bits representing the input values can give the output values.

By using logical equations, output values can be derived from input values such that the output values are those indicated by the devices' specification sheet. These logical arguments can also be implemented using AMD/OR eight-state mapping tables. For instance: the 4-16 decoder to be described later has 16 equations each of which access tables representing a four input OR gate and a one input inverter.

Extensions to the aforementioned equations will have to be created if the specification sheet only specifies certain input events. Some data sheets do not specify the results of all eight states on input, only the results of true and false. Others specify rising and falling slopes. It is still necessary for the designer to account for all eight states when creating a behavioral model since SALOGS could place these states on the input lines. Some designers simply make the outputs all undefined if any but the truth table values appear on the input. This is acceptable as long as the overall modeling goal is reached. The desire here is usually to perform logic verification. The valid inputs (in the sense of the allowed input space) could be expanded to cover any of the eight SALOGS states.

The tradeoff in core and time must be carefully considered here. A large program can take up as much core as a sizable array and run much slower than a simple table driven model. Care should be taken to simplify as far as possible not only the code but the logical equations as well. The tables which represent the eight state

OR and AND gates can be considered as free because they are accessible by more than one model.

The last method is used to model complicated VLSI circuits.

For the most complex of devices, the data books provide a functional description of the chips' operation. A FORTRAN program can then be written to describe this functional behavior. Certain results will be guaranteed by the manufacturer. These will predict the output only for certain constrained inputs. Other input events must be accounted for by the model designer. That person must decide what should happen when events outside the manufacturers' specification occur.

MODELING FOR TRUE CIRCUIT OPERATION VS. SIMULATION RESULTS

Primarily, the designer is interested in knowing whether an unspecified event has occured. This is opposed to being concerned with what the chip will actually do under that stimuli. The prefered simulation result, in general, is an undefined output given unspecified inputs.

What a chip will do outside the valid event space depends on several factors. Among these are: chip technology (MOS, TTL, etc.), configuration, and a statistical model which represents which batch the individual chip came from. By and large, designers desire a model that works the same way all the time.

A device's configuration is usually proprietary information. Therefore, it is not always possible to know how the chip is put together and thus gain an idea of what will happen given all inputs. The manufacturer only guarantees and specifies the results given certain inputs. On top of this, designers do not always want what could be a recognizable output to result from an input which should not occur. They prefer some flagging output to mark the unexpected event. This is valid when simulating for logic verification and proper system performance.

There are several ways to model a chip. This discussion has covered simple table driven models, table/equation driven models, truth table/logical equation models, and functional operation models. A technique should be chosen based on what information is available on the device, resource limitations, and the detail required.

These methods were used in this investigation to derive behavioral models for three digital subsystems. A combination of methods was found to be helpful in realizing additional savings in the amount of computer resources required to implement a particular device's model.

CH 6. A FUNCTIONAL LEVEL MODELING LIBRARY

To fulfill the idea of functional level modeling advanced by this thesis, a library of FORTRAN models was created. A 4-16 decoder, 2048 X 8 ROII, and a 256 X 8 RAM were modeled and made to interface to SALOGS. They are supported by eight state models of an inverter and a four input OR gate. These were chosen because of the immediate needs of the sponsors. These needs reflect current projects which they have undertaken. A balance was struck between core and time usage. Each model reflects trade-offs in detail, complexity, and resources as well as in the accounting for the results of input events not mentioned in the data books. All of the models were tested by writing SALOGS routines which would exercise them through the several functional operations specified by the manufacturer. The tests were then compared with the expected results. In all cases, the simulations were found to perform as described in the data books.

The remainder of this chapter will be concerned with the three models, including their construction, operation, and use. Reference will be made to their block diagrams, flowcharts, and listings.

THE 4-16 DECODER

The 4-16 decoder is discussed first because it took by far the longest time to model. Techniques had to be developed to create various kinds of models and an understanding of the realities of chip use had to be reached.

A 4-16 decoder basically performs this function: The binary value on the four input lines is read and evaluated. Depending on that binary value, one of the sixteen output lines is set low; the rest are set high. For instance, 0001 on the input would couse output line 1 to go low and lines 0 and 2-15 to go high.

As a first step in modeling this device, a large photograph was taken of its gate level diagram found in the data book [N1,1-56]. Names were then written on each node. A SALOGS gate level model was next constructed to exactly represent the photograph. This model was then tested for results, outputs vs. inputs, to derive the eight state results of all the possible input combinations.

At first a simple table driven model was attempted. Required for this was an input array 8 X 8 X 8 X 8 and an output array 8**4 X 16. It was subsequently decided that this was a bit too much core even though the simulation would execute very fast. So a truth table/logic equation driven model was tried next.

To support this a table/equation driven model of a four input OR gate was created along with a simple table driven model of an inverter. The truth table of the decoder [N1,1-58] was then implemented by a series of 16 OR gates. These gates perform as would the gate level SALOGS four input OR gate. (SALOGS models a four input OR gate using three, two input OR gates.) The equation for each decoder output line is: D+C+B+A; D+C+B+(-A); D+C+(-B)+A; ...; (-D)+(-C)+(-B)+(-A). Each decoder output line is driven by its own OR gate.

The following SALOGS code will allow the user to access the decoder:

\$MODELS

ORDECOD 0 16 4 20 8 0

OO 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15 *

AO EO CO DO

END ORDECOD

\$END HODELS

INPUT AO EO CO DO

OUTPUT 00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15

ORDECOD 00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15

AO BO CO DO

END

If using the SISL preprocessor, the user would specify:

ORDECODE 00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15; AO BO CO DO

and leave off the SALOGS \$MODELS portion.

Appendix E shows the listing of the decoder modeling software.

Refer to the Appendix and the SISL USERS GUIDE for more on

specifying models to the preprocessor.

THE 2K X 8 ROM

A ROM "Read Only Memory" is a device which has a series of binary words pre-loaded into its memory. On demand, it will place the addressed word on its output lines.

Hardest to simulate were the unspecified input events. A functional operation specification [12,6-34] provided the basis for the final creation. Sandia Lab. and decisions besed on their viewing of proprietary information as to how the device should react if unexpected inputs occured. Appendix G shows the original block diagram of the ROM, the implemented block diagram, and the operational flowchart of the model.

Appendix G also shows the listing of the software.

To access the model use the following SALOGS code:

```
$MODELS
ROM8 0 9 18 27 10 0
READY DATA7 DATA6 DATA5 DATA4 DATA3 DATA2 DATA1 DATA0 *
CLK CE CEINV ALE RDINV IOMINV IORINV
ADDR10 ADDR9 ADDR8 ADDR7 ADDR6 ADDR5 ADDR4 ADDR3
ADDR2 ADDR1 ADDR0
END ROM8
$END MODELS
INPUT CLK CE CEINV ALE RDINV IOMINV IORINV
ADDR10 ADDR9 ADDR8 ADDR7 ADDR6 ADDR5 ADDR4 ADDR3
ADDR2 ADDR1 ADDR0
OUTPUT READY DATA7 DATA6 DATA5 DATA4 DATA3 DATA2 DATA1 DATA0
ROM8 *
READY DATA7 DATA6 DATA5 DATA4 DATA3 DATA2 DATA1 DATA0 *
CLK CE CEINV ALE RDINV IOMINV IORINV
ADDR10 ADDR9 ADDR8 ADDR7 ADDR6 ADDR5 ADDR4 ADDR3
ADDR2 ADDR1 ADDR0
END
```

If SISL is to be used specify:

ROM8 READY DATA7 DATA6 DATA5 DATA4 DATA3 DATA2 DATA1 DATA0; *
CLK CE CEINV ALE RDINV IOMINV IORINV ADDR10 ADDR9 ADDR8 ADDR7 *
ADDR6 ADDR5 ADDR4 ADDR3 ADDR2 ADDR1 ADDR0

and leave off the SALOGS \$MODELS portion.

The RCM model is a FORTRAN subroatine mirroring the functional specifications found in the data book. It takes tate account proprietary information which indicates how the data of a bould react, is a inputs not contioned in its specification sheets.

THE 256 X 8 RAM

The 256 X 8 RAM was relatively easy to create. A RAM "Random Access Memory" is very much like a ROM except that it can write as well as read. Its information may indeed be pre-loaded but that information is subject to change while the system is running. Unless a new loading process takes place, the RAM will loose its stored data while the ROM will not. [II,45]

Appendix F shows the original version of the RAM, the implemented version, and its operational flowchart.

Appendix F also gives the listing of the RAM model. This model is based on that of the ROM with the added writing feature.

To access the RAM use the following SALOGS code:

```
$HODELS
RAMS 0 S 11 22 9 0
PATAL SECTION AND CONTRACT STAND DATAL BANDS
KIR I BE SEED OF SEED WITH BEST BUSINESS
ADDR7 ACOTO ADDR5 ADDR4 ADDR3
ADDR2 ADDR1 ADDR0
END RAIS
$END MODELS
INPUT RESET WRING CERNY ALE RELAW IOMING
                  ADDR7 ADDR6 ADJR5 ADDR4 ADDR3
                   ADDR2 ADDR1 ADDR0
OUTPUT DATA7 DATA6 DATA5 DATA4 DATA3 DATA2 DATA1 DATA0
RAM8 *
```

DATA7 DATA6 DATA5 DATA4 DATA3 DATA2 DATA1 DATA0 * RESET WRING CHING ALE ROLLY IOMING ADDR7 ADDR6 ADDR5 ADDR4 ADDR3 ADDR2 ADDR1 ADDR0

END

If SISL processing is to be done use:

RAM8 DATA7 DATA6 DATA5 DATA4 DATA3 DATA2 DATA1 DATA0 ; * RESET WRINV CEINV ALE RDINV IOMINV ADDR7 ADDR6 ADDR5 ADDR4 * ADDR3 ADDR2 ADDR1 ADDR0

and leave off the SALOGS \$MODELS portion.

This model also uses the functional specification modeling technique. For further detail on SALOGS and its use of models, refer to the Apiendix and the SALOGS USERS GUIDE. See Appendix H for a listing of the commands needed to bring the various SISL and SALOGS software on line. The package is supported to run on the DEC SYSTEM 10 using the TOPS-10/603A96.04 operating system.

CH 7. A REVIEW OF INDIVIOUAL FUNCTIONAL MODELING LARGUAGES

Before describing the SMLOGS preprocessor, SISL, it would be fastructive to review some of the languages which have already been created for CAD. A study of languages was undertaken to help decide on the detail required, how a language structure should be defined, and to discover a standard upon which a user interface could be based. The convenience of the user is very important as is the following of commonly accepted standards of circuit modeling. The chosen language must be expandable so that is can remain current with modern technology.

There are many levels at which one may represent a digital system.

Vertically, the following levels in order of detail may be chosen:

- electron or physics level
- discrete device
- circuit
- gate
- chíp
- functional

SISE models the structure of systems at the functional level and SALOGS simulates systems at the gate level. Together, they let the designer model at the gate, chip, and functional levels all at the same time. Horizontally, one may split the system into many or few modules or subsystems. The behavior of the total system may be studied in more or less detail by observing the simulation states which appear on the lines interconnecting the subsystems.

Many languages have been created by others working in the field.

These permit the description of exercising of digital hardware at one or more of the horizontal and/or vertical levels.

ISP (Instruction Set Processor) [S3,39]

ISP was developed to describe a computers' programming and register transfer levels. Thus, it can be used to study the behavior of a digital processor. It describes computers by using various fixed formats. Permitted are declarations and actions affecting memory, processor state, primary memory, console state, I/O state, data types, data operations, and instruction formats. Overall, it allows one to model computers at a very high level but does not describe the inner workings of the hardware beyond register transfer operations.

Additions the advantaged conventions of Add (A programming Longuage) [11,1] to describe digital hardware. Its utility comes from the partitioning of a system into a control section and a data register/logic section. The control circuit causes register transfers to take place in the data section by putting signals on its control lines. Branching information from the data section influences the sequence of the control signals.

This is a very low level, register transfer language. It does not precisely describe the structure of a digital system but simulates its output based on input. Its simulation is based on the moving of data from place to place and may be said to work at the information level.

PMS (Processors, Memory, and Switches) [\$4,42]

PMS will allow the description of computer systems in terms of the physical interconnection of a small number of elementary components. One of its main aims is to create a standard whereby designers may discuss their simulations. It can be used to focus on certain structures or register transfer and switching circuits.

The basic component types are memory, links, controls, switches, transducers, data operations, and processors. These seven components can be connected to create a eighth type called a stored program computer.

Many of the basic component types here are required in the description of digital systems in general. It would be possible to describe the behavior of a specific chip using this language. A problem is that a simulation project would be made much easier if specific elements were available which described the behavior of given devices which can be purchased off the shelf.

FST gives a designer the ability to specify logical sequences of operations without having to explicitly specify the control logic. Models are described in sequential and concurrent blocks. Any control logic is implicit in the description of a block and is produced by FST itself.

This language presents ideas which are very near to what is desired in the new language. It handles structure and operations separately and can be used at a variety of modeling levels. (A block could be an AND gate or a CPU for instance.)

LALSD (Language for Automated Logic and System Design) [S7,47]

LALSD uses a multi-level modeling approach which allows simulation at any level of detail. Designs are seen to have two parts: structure and control. It is very much like AHPL in that the control section, describing system behavior, sends signals to the structure part to initiate operations.

This language also allows the partitioning of a system into sub-blocks which can be easily integrated. It has facilities for linking subroutines to its base software. Control signals were separated from the structure for the following reasons:

- If a person is only interested in the behavior of a system, it is not necessary to study the structure.
- The control part can be implemented in hardware, firmware, or software. Thus, there is a flexibility which aids economical realization.
- Such a model is very convenient for high-level modeling such as looking at determinancy and deadlocks. Exhaustive simulation is avoided.

The general ideas behind the language are very much in keeping with the goals attempted by this investigation. It will allow working at arbitrary levels and intermixing them in one simulation.

SDL describes in detail the interconnections of a series of digital blocks. These blocks may be of any modeling level. It will also specify the interfaces between two or more subsystems. Contained in its syntax is the ability to describe node names, block names, interconnections between blocks, numbers of I/O lines, and other specifications used to fully define the construction of a digital system. In short, one could take a schematic and translate its stucture to SDL.

Because of its syntax rules, which allow the easy specification of a system structure, this language could fulfill the requirement for specifying the interconnection of elements which are at first undefined in their behavior. SDL does not intermix behavior modeling with structural modeling.

IN SUMMARY

From the above discussion, the reader will note that several of the above languages meet many of the goals as outlined in the introduction. It remains to combine the best features of each to solve the particular problems at hand. This combination is found in SISL and its interface to SALOGS.

CH 8. CHOUSING A MODELLING LANGUAGE

This happen is depoted to the description of the SALMOS proposed mor, SISL. A view of its inner details will be given along with the basic philosophy behind the language. This will demonstrate its completeness as well as its usefullness to CAD activities.

There are several requirements which have been noted by those who write description languages. These are necessary for the clear and complete specification of a digital system. [D5,1]

- ability to name and describe blocks which correspond one-to-one with those of the system being designed
- 2. separation of process and control
- 3. support for several modeling levels
- 4. separation of the various phases of simulation and testing
- 5. allowance of concurrent activities at the several modeling levels
- 6. specification of synchronous and asynchronous activities
- 7. description of data routing between elements

To these may be added:

- 8. support of the user in his attempts to describe a system
- 9. easy interfacing to other design packages
- 10. following of standards which are generally accepted in the design community

The choice made for a language to support the intermixing of functional and gate modeling levels was based on the above criteria. SDL was chosen for the basic spaces of structural sodeling and SMIOCS was chosen for process control. (See Appendix D for a description of SALOGS.) The review of the other languages was used to create SISL which combines syntax features of SDL and SALOGS. It extends the modeling capabilities of SALOGS by making it much easier to use beyond the gate level.

The syntax of register transfer level, programming level, and information level modeling did not appear to be conducive to the intermixing of widely separate design levels. However, the general ideas presented by the other languages were valuable in the effort to derive the new language, SISL.

The details availsable on SDL were sufficient for an in-depth study of that language. Also, its syntax is very close conceptually to such languages as PCAP (Princeton Circuit Analysis Program) [S8,1] which is a discrete component level circuit simulation package. Many practicing engineers began by using similar design aids. An intuitive feel for SDL's use can be easily developed since it is "natural" to a human user. SDL's syntax works very hard for the designer.

Thus, a subset of SDL was chosen to begin the construction of SISL's syntax. It was modified slightly to conform more closely to that of SALOGS and to cover some areas that might help the user make fewer errors when describing a system. (More on this later.)

SISL it self her no ability to define a process, that resides in SALOGS. (
It lets one describe the structure of arbitrary (functional) level digital systems and their interface to the gate level portion of those systems.

SISL simply adds to SALOGS the ability to easily describe structures of a functional level in addition to its gate level without having to do

FORTRAN coding or to become involved with the details of SALOGS'

\$MODELS section. (See the SALOGS USERS GUIDE.)

The SALOGS/SISL system separates process and control. The process is the behavioral model of the functional element written in FORTRAN. Control resides in the structure of the digital system. A behavioral model may be changed at will (as long as the number of I/O lines remains the same) without the need to modify the system structure.

^(*) For further detail refer to the SISL USERS GUIDE.

basic maining syntax in follower. This package is modular in and it has the following fitter to earlie the combination of functional and gite level structures, routines to compile the combination of functional and gite level structures, routines to compile the exercising commands, routines to perform the exercising commands, and routines to perform fault analysis.

SISL SYNTAX

Appendix B shows the syntax of SISL. There are two differences between it and that of SALOGS.

- A ";" separates the list of output nodes and input nodes. This is to force the user to carefully consider line assignments. When one may specify up to 40 nodes per element, this becomes necessary. Also, it provides an aid to the user proofing of the structural description.
- A "*" as the first character rather than only in column #1 flags a comment line. This is a user convenience and allows creation of banners without the need for an extraneously filled column.

The syntax rules are not as extensive as that for SDL, the model for SISL, since only the interconnection of pre-defined elements is considered. However, SISL is complete and will allow the description of system structures where the elements contain up to 40 I/O lines each. This limit had to be set due to SALOGS' internal restrictions. SISL is designed to interface easily with SALOGS.

Sixt is its the more through its constitle decimal country rules, though its error of intertace to 5400GS, and through its user proofing. It is friendly and does not take long to learn. Also, being modular in its construction, modifications and additions are not difficult to make.

User proofing is perhaps the most important feature of a package which is meant for release to those who have no need to understand the inner workings of the software. Basically, a philosophy of error checking should include the detection of problems at the earliest possible point in the program. Errors should not be allowed to propagate beyond their point of earliest detectability. Too,

The user must be able to determain whether failure of an attempted operation was due to improper control signals or system malfunction [P3,13].

If "...improper control signals..." is replaced by "...improper user input data...", an idea is obtained as to how to approach the delivery of error messages.

While SISL will not catch all conceivable user errors, it will note errors due to syntax violations and inconsistencies. These include a node being used for input but not for output and an incorrect number of 1/0 nodes for an element.

SIGHT is in the error toral defendables and following the same converts the syntax to that required by the SALOGS \$2000 LS portion.

This can be a rather extensive conversion line SALOGS regulars quite note to set up a structure at the functional level. (See Appendix A for an example.)

No node name conversions are made although SISL will check the correspondance of numbers of 1/0 lines and the naming conventions. It will also ensure that each node is used at least once for input and for output. During the parsing of the several syntax diagrams, SISL will check the integrity of each. Any error will result in a message and an immediate controlled termination. The syntax diagramming, which guides the parsing of user input, is based on that for the computer language,

PASCAL [J2,1]. The procedure is the author's original design Each line of input data is dealt with as a single entity. It is not necessary for SISL to know what went before or what comes later. A lines' syntax is translated and then spooled to a scratch file which eventually becomes the \$MODELS heading for the SALOGS gate level portion of the overall system description.

Node names are retained as is so that throughout a complete simulation, the designer will not be troubled with several words which stand for the same thing. The intent has been to case the burden placed on the user during the design process.

CH 9. PROJECT GUTTARY AND CONCLUSIONS

The objection of the distribution of state of the master of the art by the creation of SISD, a functional level preprocessor to the gate level SALOGS CAD package, and a library of three behavioral models. The state of the art has been advenced because the sponsors will now be able to support projects previously denied due to the DECSK modeling limitations. An easy mix of functional and gate level modeling has been achieved. A designer may directly intermix the two levels of modeling while saving main memory and time. The assumption here is that a behavioral model of a system element will perform faster and in less main memory than its gate level counterpart. It will deliver less detail, but the extra detail is not desired by most designers modeling at levels beyond the gate level.

The group of possible users include all of the institutions presently making use of SALOGS. These include several universities and industrial concerns as well as the two sponsors.

SISL is presently running on the AVIONICS LABS DEC SYSTEM 10 and the SANDIA LABS DEC SYSTEM 20. It has proven itself a great aid in the modeling of digital systems. Continuing support will be carried out by the author (see VITA for address) through SANDIA LABS.

しまる あるこ

Any individual wieldow to extend this study should look to the creation of additional behavioral sales as a will interpose to 125.0%, include of any modelfy postage (see, as bedeen account the analogy) and types of stemate account for the first the same and types of stemate account for the first and a country of the sales and enign all.

An extensive library would mean that FORFRAN coding would not have to be done to include an element in a system model. The timing question should also be addressed. As digital systems become faster and faster, the timing issue increases in importance.

Presently, only the following are in the behavioral library: a four input OR gate, 4-16 decoder, 2K X 8 ROM, and a 256 X 8 RAM. An ALU would be encouraged by the sponsors as would a CPU. An extensive timing buss would also be valuable.

Anyone wishing to use or extend the features of SISL or its behavioral library should feel free to contact the author or the sponsors.

CAUTION ON FILES.	63

SISE, Structural Interface to the SALOGS (Saulia LOGIC Simulator) which functional level preprocessor to SALOGS (Saulia LOGIC Simulator) which is a gate level digital simulator. SALOGS simulates digital systems using AND, OR, and INVERT primitives. These primitives or gates perform during the simulation almost the same as do their MOS technology counterparts. Eight signal states are used to partition voltage levels. These eight states include the logical states. Refer to Appendix D of of this guide for more on the application of and the terms applied in in relation to SALOGS.

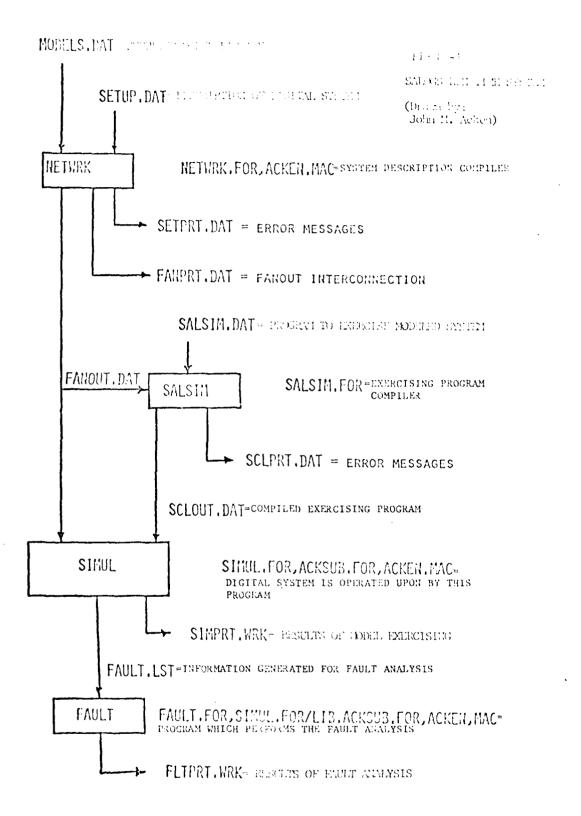

The purpose of SISL is to allow the description of a digital system in terms of high level devices such as adders, shift registers, etc. rather than in gates such as AND, OR, etc. This level of description will be refered to in this manual as macro descriptions. The term gate level simulation is used here to refer to digital simulation using MOS technology behavior models of AND, OR and INVERT eight state primitives. The several algorithms attendant to SISL perform their preprocessing by implementing a digital system description language very close to that of SALOGS itself. Thus, the designer will find the use of this new level of modeling quite easy to transition to if he has gained a familiarity with the SALOGS design aid.

Not only can the designer work at a very high level of system description but he can link a gate level SALOGS model to a SISL macro model and run the entire network as one system. This quide assumes the users' knowledge of SALOGS. Appendix D of this quide contains a copy of the most recent users guide to that package.

SISE is designed to run as a functional level preprocessor to the gate level SALOGS modeling software. It will accept functional level descriptor information and return the SALOGS parameters required to create a single entity from the functional and gate level portions of a digital systems' model.

Fig UG-1 shows the run time data and control flow for SALOGS.

Obviously, this design software runs as a series of batch programs interfaced through a number of disk files. Fig UG-2 shows how SISL is an added program (preprocessor) to the SALOGS series. The user creates two model files. One holds the SISL macro model portion of a digital system and the other holds the gate level portion. These two files are manipulated by SISL to produce a total network description to be processed by SALOGS. SISL does not produce gate level models for the large scale devices. Rather, it creates linkages to FORTRAN IV behavior models. These behavior models (called functional models in the SALOGS literature) determine how the device operates and the technology involved. They are not required by SISL itself.

Single lines are data flow.

Double lines are control flow.

STRUP.DAT SALOSS esta lavel terription. SISE adds on the SALOGS fine local and legical models to this file. This file is sent on to SALOGS.

SISL-DAY: The description of the functional level digital system.

SISL.NAM: A list of device names and their individual number of I/O lines and internal subroutine names.

SISL.OUT= All messages generated by SISL during its last run.

SETUP.DAT----> SISL.OUT SISL.NAM----> SISL.OUT SISL.DAT----> SETUP.DAT SETUP.DAT ----> SALOGS

FIG UG-2
SISL RUN TIME SYSTEM

developed by W.M. Van Cleemput for his SDL or Structural.

Description Language [V2,1]. For all the seeming complexity,

the source code for STSL is only 1100 lines of FORTRAN IV. Appendix C

of this guide contains the listing of the software. Appendix B of this guide gives the set of syntax diagrams which completely define this language.

One need only study these constructs to understand the syntax.

AN EXAMPLE

To demonstrate the use of SISL, a complete run will now be presented. Fig UG-3 is an example of the block diagram of a digital system. In the next section examples will be given of each file required to program it.

There are several steps required to build a functional/gate level model. These steps are:

- 1. obtain the gate diagram for the gate model
- 2. code this model in the SALOGS gate level language
- 3. test for compile and execution errors of this model
- 4. decide on the functional level additions to the gate level model
- 5. write the SISL functional level portion of the overall model
- 6. test this portion for compile errors
- 7. run a test on the total functional/gate model
- 8. repeat steps 1-7 until results are satisfactory

The gate level portion of this system consists only of an AND gate. Since the designer is assumed to already have some expertise with SALOGS, we will only discuss the SISL requirements of the system.

FIG. VC-3

Three files are required as input to the SISE preprocessor. These files provide the information required by SISE at run time. Following is a list of those file, descriptions of their required format, and a sample of each. Together, these file demonstrate the programming of the block diagram given in Fig UG-3.

SETUP.DAT

The SALOGS gate level portion of the intended digital system; SISL adds to this file the linkages to any required behavior models. Refer to SALOGS USERS

GUIDE for the details of gate level modeling. SISL assumes that this file originally contains no \$MODELS section.

Original version (created by user):

INPUT A B C
OUTPUT K
AND K H I J
CIRCUIT H I J A B C
END

Final version (created by SISL):

\$MODELS COUNTUD 0 2 FED ABC END COUNTUD BTOG FED HIJJ END BTOG CIRCUIT 3 6 0 1 C COUNTUD F E D A B C BTOG H I J $F \in D$ END CIRCUIT \$END MODELS INPUT A B C OUTPUT K AND KHIJ CIRCUIT H 1 J A B C END

SIGH. DAT

the Rescription of the macro portion of the digital x_1, \dots, x_n by it, takes, such a size usel in the astrock. Is conflored along with its attendant I/O lines in this familion:

DEVICE A ME (SPACE) of TRIST (SPACE); (SPACE) INLIST where

OUTLIST is the list of nodes forming the output from the device and INLIST is the list of inputs to the device.

The first non-comment line of this file is:

CONNECT(SPACE)OUTLIST(SPACE); (SPACE)INLIST where

OUTLIST is the list of macro model outputs

to the gate model and INLIST is the list of inputs

coming from the gate model.

* THE SECOND TEST OF THE SISL/SALOGS TRANSLATOR

CONNUCT H I J ; A B C COUNTUD F E D ; A B C BTOG H I J ; F E D END

Continuations are noted by using a space followed by a "*" at the end of the continued line. A line may be continued from any point where a space occurs. Comment lines are noted by having a "*" as the first character of a line. An example of a continuation follows:

ABC

SISL. MAM

A list of all the allowed high level devices and certain parameters unique to each one. Every high level device usable by SISL and having code in the behavioral library is listed in this way:

LINE 1-- Devicensme (col 1-8), i ft justified to column one

LINE 2-- number output nodes required (col 1-5)

number input nodes required (col 6-10)

SALOGS functional model number (col 11-15).

All numbers are integer and right justified.

BTOG 3 3 1
COUNTUD 3 3 2

SISL OUTPUT FILES

SETUP.DAT The combination of SALOGS gate, functional, and logical models created by SISL. This file contains the total system to be simulated and is passed on to SALOGS.

SISL.OUT All messages generated by SISL during its last run. Each message is of the format:

SUBROUTINE GENERATING MESSAGE, FORMAT NUMBER, and MESSAGE Fig UG-4 gives an example of this file.

an output/Input node.

FIG UG-4 AN EXAMPLE OF SISL.OUT

SISE TERPORARY PIERS

SISE uses two iffes, TERF and TERP2, for working storage, those files are created and deleted during any given run.

CAUTION ON FILES

Any file used for output by SISL should always be backed up by the user prior to each run if the current version of that file is desired for retention. This is particularly true of SETUP.DAT since it is used first by SISL as the gate level portion of the digital network and then to contain the total system description.

SISL LISTING

EACH SUBROUTINE IS PRECEDED BY ITS OWN OPERATING FLOW CHART.
THE FLOW CHARTS PORTRAY THE ALGORITHM USED FOR EACH ROUTINE.

In all the software, liberal use is made of certain functions which may not perform the same way on all computers:

OPEN, CLOSE are used for disk file handling.

•AND., •OR. are used on integer variables for data packing and and unpacking. These depend on a shift left being caused by 1 = 1/2 and a shift right being caused by 1 = 1/2 where I is an integer variable.

 $J={}^{n}K$ places the non-decimal octal value K into the integer location 1.

JIRRY D. SZUBELEZ

SALOGS IV IS THE SANDIA LOGIC CIRCULT SIMULATOR. THE LOGIC CIRCUIT TO BE SIMULATED MAY CONTAIN LOGIC GATES, LIBRARY LOGIC MODELS, USER DEFINED LOGIC MODELS, AND/OR USER DEFINED FUNCTIONAL MODELS. SIMULATION IS CONTROLLED BY SPECIFICAGE INPUTS TO THE CIRCUIT, TIME STEPS, CONDITIONS OF SIMULATION, AND WHAT IS TO BE PRINTED OUT DURING OR AFTER SIMULATION.

THE LOGIC MODELS ARE WRITTEN IN A NETWORK DESCRIPTION LANGUAGE (NOW), THE FUNCTIONAL MODELS CAN BE WRITTEN IN FORTRAN, AND THE SIMULATION CONTROL IS WRITTEN IN SALSIM.

SALOGS HAS BUILT-IN LOGIC GATE DEFINITIONS FOR THE OPERATIONS OF: AND, OR, NAND, NOR, ENGLUSIVE-OR, INVERSION, WIRED-OR, WIRED-OR WITH A PRIORITY, TRANSMISSION GATES, BUFFERS, AND MULTIPLENERS. LOGIC GATES, LOGIC MODELS, AND FUNCTIONAL HODELS MAY BE FRELLY LATERMINED IN A GIVEN CIRCUIT.

GLOSSARY

- In the state of th
- Black bo. . function I forch of refulling which ignores the future contents of a given redule. This route simply delivers as output the the "SE, re" word or the delast word.
- Core- a compaters' unique very. This nain ladded sump-out disk storage space and mesons from a leb instruction are directly executed.
- Chi Time- time spent by the central processor during the execution of a given jou.
- Functional level modeling- specifies the connections between behavioral models. It will employee the employing the employees structural and behavioral modeling.
- Gate level modeling- modeling using the basic logical primitives such as AND, OR, Mode, etc. fair level is more concerned with the actual operation of a chip given undefined injuts.
- Intermix- to use two or more ideas, or simulations at the same time.
- Library- a series of comparer subprograms accessible by any number of calling programs. These posterm contain operations with are common to the calling programs.
- Link- to easiest to. We can couput a program in loaded into momony, it can constitute out olde the parts of which have been written independently of it.
- Logical link- Program rebreatings can be called in any given order. One must define that order as well as make the subroutines available to the calling program.
- Micro-perhaps the most confusing word. As a level of modeling, it refers to the bar pleaser of the interconnections and periods are of the subspections. As a piece of mottware, it is a block of code which the confider or as coder can place at any of second up which levations of a progen.
- Parsing— the procedure by which the phrases in a string of characters are accordated with the cosponent process of the language grant or which generated the string [ks, 1044].

- Register transfer modelings a deling the operacles of a digital system being crying, seem and when data is passed.
- Rom With Spiritus (Via openha) asserting explorate finance of Historian formula to the second of the
- Structured level webling- delines the interconnection of algorithm.
- SEC 10 Words- A SALOOS mode may be given a stradingly never to change value by the designer. This value will recain regardless of the simulation produced value.
- Subsystem- a part of a complete digital unit. For example: a ROA is a subsystem to a computer manager.
- Wall Time— the total time the computer has control of a given program. This time s_i as the resent a job first enters the execute queue and the moment it enters the final octput queue.

Peter G. Raeth was born on 10 July 1951 in Jackson Michigan, the son of Nicholas Conrad Raeth and Theresia Roehm Raeth. In 1970 he enlisted in the United States Air Force. He was Honorably Discharged in 1976. In 1975 he graduated from the Trident Technical College at Hanahan South Carolina with an Associate in Electronics Engineering Technology. That same year he began the four year engineering program taught by the University of South Carolina at Columbia. During the period 1975-1979 he studied digital engineering, attended USAF-ROTC, and worked as a free-lance consultant in software applications, twice publishing his research. In 1979 he graduated with a Bachelor of Science in Electrical Engineering and was commissioned a Second Lieutenant USAFR. He is a member of Tau Beta Pi, Eta Kappa Nu, and Omicron Delta Kappa. His first assignment was to attend, in residence, the Masters program in Computer Engineering given by the Department of Electrical Engineering of the Air Force Institute of Technology at Wright-Patterson Air Force Base Ohio.

A STATE OF THE STA

There is a space by a formula of a substant formula the first substantial subs

 $\mathcal{A}_{i}(x) = \{x_i \in \mathcal{A}_{i} \mid x_i \in \mathcal{A}_{i} \mid x_i \in \mathcal{A}_{i} \}$

Therefore counct be an although a life, in part for dead and particles as a Life livel. As a inclinate or observe a functional level preprocessor as in furthermy functional device resets blaked to a gate level simulator's input tan use. This permits the mixing of behaverial models with gate level models in the same system structure. The combination of processes (element models or primitized) and their structure (interconnections) can be exercised all at one time during a single significant receion. From the start, there came forth an obvious method which could be used to intermix the several levels of modeling.

Two apparate pieces of software were written to implement a specific solution to the above stated situation. SISL, Structural Interface to the Salogs but, more was creeted. This is a functional level prepries sor to SMOGS (SAndia trule Singleton) which is an eight-state, NOS, yete level digital systems sinutions. SISL will accept functional level syst as descriptions and convert them to a form the ptoble to SMOGs.

The effect effort was the building of a functional level modeling library. This library consists of three behavior models: a 4-16 decoder, a 2048 x 8 ROY, a 256 x 8 ryt. These conclusive decimed to be used in a functional level/mare been model or a digital system and will link to the SALO S run time system. The other, the setwo program (SISE and the modeling library) provide the easy and of the residence content to digital system design.
